

Technical Assessment Reflection

The project is organized into four main areas: Player, Visuals, Data, and Gameplay Systems. Since the player interacts with most of the game's functionality, I placed all player-specific scripts in their own assembly, allowing them to depend only on the systems they require. This keeps the player logic focused while reducing unnecessary coupling. Likewise, systems such as the Inventory and Interactables have their own assemblies because they are largely self-contained and expose only the APIs needed by the rest of the project.

My goal was to separate gameplay logic from presentation as much as possible. The UI acts as a reflection of the game's state, receiving events and invoking public methods from other systems, while the gameplay systems remain completely independent of the UI. I followed the same philosophy for other visual elements to keep presentation and functionality isolated. Regarding data, I tried to make the project as data-driven as possible. Because of the time constraints, some text and configuration remained inside scripts or scene objects. A more complete solution would move this information into dedicated data assets or localization systems.

I really liked that this assessment took into account more than just programming skills. It also evaluated the ability to consider other essential aspects of game development, such as game design and visual aesthetics. Most of the time, this is exactly how I develop games. It is valuable for every member of the team to be aware of the game's vision and what it needs to achieve the desired feeling and aesthetic.

At the beginning of the assessment, one of the biggest challenges was deciding how to prioritize my time. Every hour spent improving the visuals or polishing the player experience was an hour I wasn't sure I should spend instead on writing cleaner code. Finding that balance was probably the biggest challenge of the assessment.

In the end, I believe I successfully met the requirements while also paying attention to the overall player experience within the available time. During the final hours, I deliberately prioritized delivering a complete experience. Because of that, I made a few pragmatic decisions, such as reloading the scene to handle the player's death or hiding the player during a Timeline sequence, that allowed me to deliver a complete experience within the time constraints. Overall, I think the result is solid both from a technical perspective and from the player's point of view.
